

Get the latest release, and have it know it is the latest

ozwala.com's releases page says which release is current and serves it at /releases/latest/download. The CLI a member downloads from there, and the desktop app built the same way, must say they are that version -- so the releases page is not a page that merely looks right, and a bug report that quotes `ozwala version` names a real release.

Get the latest release, and have it know it is the latest

ozwala.com's releases page says which release is current and serves it at /releases/latest/download. The CLI a member downloads from there, and the desktop app built the same way, must say they are that version -- so the releases page is not a page that merely looks right, and a bug report that quotes `ozwala version` names a real release.

The harness builds the release as .goreleaser.yml does, with its own flags and ldflags, standing in version 0.99.0 for the git tag. Whatever version the release injects, or fails to, is what these steps see.

What you can count on

- ozwala.com names its latest release, and /releases/latest/download serves exactly that build
- The CLI downloaded from ozwala.com reports the version the site says is current
- The desktop app, built as the release is, shows the version the site says is current

Where it works

On ozwala.com, in the desktop app, and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
