

Follow releases, pin a version and hold it, and unpin

An installed jig follows its repository's releases. Before the first release it follows the latest commit and says so; after it, a push that is not a release does not move it. Pinned to an earlier version it stays there through updates and auto-update -- which is how you go back to one -- and unpinned it moves to the newest release.

Follow releases, pin a version and hold it, and unpin

An installed jig follows its repository's releases. Before the first release it follows the latest commit and says so; after it, a push that is not a release does not move it. Pinned to an earlier version it stays there through updates and auto-update -- which is how you go back to one -- and unpinned it moves to the newest release.

What you can count on

- Before any release, an update moves to the latest commit and says there are no releases yet
- After the first release, an update moves to it, and a push that is not a release does not move it
- Pinned to an earlier version, the jig stays there through an update and an auto-update
- Unpinned, it moves to the newest release

Where it works

In the desktop app and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
