Sign a script in with a personal token, and revoke it

A member who publishes from a pipeline cannot click Allow in a browser every time it runs. Instead they make a personal token on their ozwala.com settings page and give it to the script in OZWALA_TOKEN, which the CLI uses in place of any stored sign-in.

The token is the member's to end: once they revoke it on the same page, the script that holds it is signed out, with no change on the machine where it runs.

What you can count on

- A member makes a personal token on their settings page, shown once
- A script given the token in OZWALA_TOKEN is signed in as that member
- The member revokes the token on their settings page
- Once revoked, the token no longer signs the script in

Where it works

On ozwala.com and on the command line. Each of these is checked, on every surface named, by the ozwala-usecases harness.
